## BONAFIDE CERTIFICATE

Certified that this project report "Developing Database of Inhibitors against JNK Isotypes for analyzing Specificity of Scaffolds against these Targets" is the bonafide work of "PREETI RANA \& ANKITA GUPTA" who carried out the project under my supervision.

Dr. Chittaranjan Rout
Date :

Associate Professor

Department of Biotechnology and Bioinformatics

## ACKNOWLEDGMENTS

Working on this project was a source of immense knowledge to us. We would like to express our sincere gratitude to Dr. Chittaranjan Rout and Research Scholars Ms. Nupur Munjal, Mr. Deepak Mishra for their guidance and valuable support. A huge thanks to Research Scholars Mrs. Deepshikha Rathore and Ms. Babita for validating our data. A special thanks of gratitude to Mr. Shubham Singla for his technical support. We acknowledge many helpful comments received from other faculty members for improving the material and methods of our project. This work would not have been without the guidance and help of several individuals who in one way or another contributed and extended their valuable assistance in the preparation and completion of this study.

We also want to acknowledge Assistant Professor Dr. Ram Singh and Department of Applied Chemistry, Delhi Technological University for their technical support.

Thank You.

## SUMMARY

The JNK inhibitors against Alzhmeir disease (AD) should be efficient when they modulate the JNK activity for treatment of AD without affecting other cells. Though some inhibitors were reported but using for them for treatment lead to side-effects and toxicity. Further, the current JNK inhibitors inhibit all JNKs because of highly similarity between the isotypes which may lead to further complications. Thus, we need specific JNK inhibitors that provide both cell type and signal specificity. Present study is intent to develope a database of inhibitors (AlzID) active against AD promising drug targets JNK isotypes collected from published literature. This database contains over 650 molecules and their activity data ( $\mathrm{IC}_{50}$ values) against three JNK enzymes. Optimized 3D geometries are provided to allow virtual screening. Geometry of each inhibitor is optimized using B3LYP (Becke's Lee Yang and Parr correlation) approach. The inhibitors were annotated with their molecular properties such molecular weight, LogD, LogP, asymmetric atoms, number of rotatable bonds etc. Other information such as SMILES, IUPAC name, etc. were also provided. To determine common and specific fragments, each inhibtors were fragmented on the basis of Bemis Murcko method i.e. ring, side-chain, linker and framework (to find which fragment exist and how frequent are they). We identified the fragments that were occurring more than random in a dataset. Based on the frequencies of fragments in dataset, we identified common and unique fragments for JNK isotypes. The inhibitors data were provided with several common file formats including SMILES, SDF and mol2. A molecular drawing interface (JME) and RPackage 'rcdk' was incorporated into the database to facilitate searching of molecules on the basis of similarity. Text-based query is also available. Access and retrieval of data through similarity based searching and text-based method are available. This database also allow user to upload/draw desired molecules for searching. User can also get library of molecules for virtual screening that are specific against a particular JNK isotype.

## CHAPTER - 1

## INTRODUCTION

Alzheimer's disease is an irreversible, progressive brain disorder that slowly destroys memory and thinking skills, and eventually the ability to carry out the simplest tasks Alzheimer's is the most common cause of dementia among older adults. More than 4 million people in India have some form of dementia. Worldwide, at least 44 million people are living with dementia, making the disease a global health crisis. It is not a normal part of aging, although the greatest known risk factor is increasing age, and the majority of people with Alzheimer's are 65 and older. This is expected to double by 2030. Despite the magnitude, there is gross ignorance, neglect and services are scarce for people with dementia and their families.

### 1.1 Mechanism of Alzheimer Disease (AD)

AD is a neurological disease which causes death of brain cells that ultimately lead to memory loss and cognitive decline. The disease is characterized by cognitive impairment, progressive neurodegeneration and formation of amyloid-beta containing plaques \& neurofibrillary tangles composed of hyperphosphorylated tau. The disease can initially be characterized by synaptic damage accompanied by neuronal loss.

The main thing lead to Alzheimer is the formation of a peptide known as Amyloid beta which clusters into Amyloid Plaques that leads to killing of neurons which further causes dementia (Fig 1.1).

There are two forms of amyloid beta peptides :- 40 and 42 amino acids. Enzymes that cleave Amyloid precursor protein (APP) are called Secretases. Alpha-secretase and Beta-secretase are two enzymes that initially compete to cleave the APP. Amyloid-beta formation does not take place if a-secretase cleaves APP. But if beta-secretase cleave APP then it can further be cleaved by gamma-secretase to form either a 40 amino acid Amyloid Peptide $\left(A B_{40}\right)$ which is soluble \& mostly innocuous or a 42 amino acid peptide $\left(A B_{42}\right)$ which clumps together to form insoluble Amyloid Plaques.

Processes playing important role in causing death of neurons during Amyloid Plaque Formation as follows :

## I. Infammatory \& oxidative damage

## II. Neuro-fibrillary tangles

Astrocytes and Microglia are two major types of brain cells that participate in inflammatory response. The former become more numerous in AD and produce Prostaglandin acid after activation which mediate inflammatory response. Microglial cells after activation produces damaging free radicals. Activities of both brain cells cause death of neurons.

Fig. 1.1: Disease process of AD Formation of neuro-fibrillary tangles (NFTs) leads to memory loss

[^0]Amyloid precursor protein -> Fibrillar Amyloid-Beta and Oligomers -> Amyloid Plaques -> Inflammation \& Neuro-Fibrillary Tangles -> Neuron Death and Synapse Loss

### 1.2 Treatment

AD is a complex disease and not one drug or single intervention can treat - it successfully. Current approaches are focusing on maintaining mental function, behavioural and slowing down the symptoms of AD. The following are few FDA approved drugs used for the treatment of AD :

## FDA -Approved Drugs for Alzheimer's Disease

| Drug | Class \& Indication | Mechanism of <br> Action | Common Adverse <br> Effects |
| :--- | :--- | :--- | :--- |
| Donopezil | Acetyl Cholinesterase <br> (Ach) inhibitor <br> recommended to treat <br> symptoms of mild to <br> moderate and moderate <br> to severe AD | Halts the breakdown <br> of ACh in brain | Vomiting, Nausea, <br> Diarrhoea; |
| Galantamine | ACh inhibitor <br> prescribed to treat <br> symptoms of mild-to- <br> moderate AD | Halts the breakdown <br> of ACh and thus <br> release more <br> acetylcholine in brain <br> after stimulating <br> nicotinic receptors | Nausea, Diarrhoea, <br> vomiting, loss of appetite, <br> weight loss; |
| Memantine | NMDA antagonist <br> recommended to cure <br> manifestation of <br> moderate-to- severe of <br> AD | Prevents the toxicity <br> associated with <br> excess glutamate and <br> regulates its <br> activation | Dizziness, confusion, <br> headache, constipation; |
| Rivastigmine | Cholinesterase inhibitor <br> recommended to cure <br> manifestation of mild- <br> to-moderate AD | Checks the <br> breakdown of ACh <br> and BCh in brain | Nausea, Diarrhoea, <br> vomiting, loss of appetite, <br> weight loss, <br> Muscle weakness; |

As given above these drugs have enough side-effects and sometimes these side-effects lead to other diseases.

### 1.3 Drugs in Research, Targets and their Shortcomings

The followings are few drugs that are in different stages of clinical trials. But they also produce major side-effects.

| Drug | Mechanism of <br> Action | Stage of <br> Development | Common <br> Adverse Effects |
| :--- | :--- | :--- | :--- |
| Solanezumab | Beta-Amyloid | Phase -3 | Nasopharnygitis, <br> Diarrhea and <br> increased blood <br> Creatine <br> Phosphokinase |
| Verubecestat | Beta-Secretase | Phase -3 | Signs of Liver <br> Toxicity, Changes <br> in Blood Glucose, <br> Fur <br> Depigmentation |
| AADvac1 | Tau | Phase -2 | Allergy |
| CSP-1103 | Beta-Amyloid, <br> Inflammation | Phase -2 | Mild Diarrhea |
| Intepirdine | AChE <br> Neurotransmitter | Phase -3 | Acute Toxicity |

AChE: is the primary cholinesterase in the body. It is an enzyme that catalyzes the breakdown of acetylcholine and of some other choline esters that function as neurotransmitters.

BChE: is a nonspecific cholinesterase enzyme that hydrolyses many different cholinebased esters. In humans, it is made in the liver - and found mainly in blood plasma.

### 1.4 JNKs are Considered Better Targets

The c-Jun N-terminal kinases belong to sub-family of MAPK (Mitogen-Activated Protein Kinase). Activation of JNK pathways causes natural death of cells during development as well as for pathological death that is associated with neurodegeneration disease. Side-effects of Alzheimer drugs are reported as major obstacle in the path of successful treatment. The cJun N-terminal kinases (JNKs) have major role in stress signalling pathways and the JNK3isotype is expressed mainly in neuronal tissue. The JNK3 enzyme is highly expressed in postmortem brains of individuals that suffered from AD. This enzyme has been found to play an upstream role in neuronal ischemic apoptosis. The loss of JNK3 protects the adult brain from glutamate-induced excitotoxicity and therefore, this enzyme is a promising drug target. However drugs targeting JNK3, due to similarity of this enzyme with other JNK-isotypes, are expected to produce side-effects. Consequently, the development of selective JNK3 inhibitors represents a useful approach may bring better treatment outcomes. Therefore, this resource has been developed to provide unique and common active fragments against drug targets of AD.

The selective expression of JNK3 in the brain, and the findings report that JNK3 knockout mice exhibit amelioration of neurodegeneration in animal models of AD, suggest that the inhibition of this isoform would be a promising therapeutic option.

Uncontrolled proliferation, cellular growth and relocation along with deregulated angiogenesis causes generation of malignant tumors. JNK signal reduction pathway may not act exclusively in apoptosis, sustained JNK activation leading to activation of AP1. This activation has recently been implicated to contribute to cellular survival of specific cancer types such as glial tumors and BCL-ABL transformed B-lymphoblasts.

In glial tumors, over-expressed JNK/AP1 activity was seen in most of tumor samples of primary brain. For transformed B lymphocytes, BCL-ABL was exhibit to activate the

JNK pathway which further up-regulate the expression of anti-apiptotic bcl-2 gene.
JNK isoforms have the following tissue distributions:
I. JNK1 and JNK2 are found in all cells and tissues.
II. JNK3 is mainly expressed in the brain, but is also expressed in very less amount in the heart and the testis.

Therefore, highly selective drug developed against JNK3 can only bind to JNK3 expressed in brain. The selective drugs have lesser chance to interact with other proteins present in different tissues.

In brain tissue and cerebrospinal fluid collected from AD patient, JNK3 is highly expressed and activated. It is a crucial kinase for phosphorylation of Beta- APP at T668. Genetic depletion of JNK3 resulted in reduction of $A B_{42}$ peptide level which leads to increase in number of neurons and improved cognition.

JNK3 activation is integrated with the increased levels of NFT's and senile plaques (Fig. 1.1). This enzyme directly modulates the formation of NFTs by immediate phosphorylation of Tau. It has highest affinity toward phosphorylation at Ser, thus it can strongly autophosphorylate itself and contributes to hyperphosphorylation of Tau.

### 1.5 Difference between CNS and Non-CNS Drugs

| Molecular Properties | CNS | Non-CNS |
| :--- | :--- | :--- |
| MW | $319(151-655)$ | $330(163-671)$ |
| ClogP | $3.43-(0.16-6.59)$ | $2.78-(-2.81-6.09)$ |
| ClogD | $2.08(-1.34-6.57$ | $1.07(-2.81-5.53)$ |
| H bond donors | $0.85-(0-3)$ | $1.56-(0-6)$ |
| H bond acceptors | $3.56(1-10)$ | $4.51(1-11)$ |
| Rotatable Bonds | $1.27-(0-5)$ | $2.18-(0-4)$ |
| Aromatic rings | $1.92(0-4)$ | $1.93(0-4)$ |
| Molecular Volume $\left(\AA^{3}\right)$ | $800-1000$ | $1000-1200$ |
| Topological Polar Surface Area <br> $\left(\AA{ }^{2}\right)$ | $<76(25-60)$ | $>80(80-140)$ |

Table 1.5.1 : Difference in molecular properties of CNS \& Non-CNS drugs

In contrast to other drugs, the CNS drugs should posses some unique characterstics due to blood brain barrier (BBB). For a CNS drug to achieve optimum therapeutic efficiency, it should possess high degree of potency and selectivity for interaction with the target.

### 1.6 JNKs Require Specificity

Although several JNK inhibitors have entered clinical trials, the initial pace of advancement and potential success seems to be limited for a variety of reasons. The fundamental reason is that these inhibitors cannot directly serve the purpose of modulating JNK activity for treatment of AD without affecting other cell types, as the JNKs mediate several signalling pathways in multiple cell types, thus, use of these compounds for treatment can lead to other side effects and toxicity. Further, the current JNK inhibitors inhibit all JNKs because of highly similarity between the isotypes which may lead to further complications (Fig. 1.6.1). Therefore, generation of JNK1, JNK2 and JNK3 specific inhibitors are required to trigger the problem of specificity. Thus we need specific JNK inhibitors that provide both cell type and signal specificity. This can be generated only if the specific interacting partners affecting specific cellular processes in disease are clearly defined. Hence, specificity is a critical issue that needs proper evaluation for successful JNK inhibition therapies.

The JNKs consist of ten isoforms obtained from three genes: JNK1 (four isoforms), JNK2 (four isoforms) and JNK3 (two isoforms). As there is highly similarity between sequences of JNK1, JNK2 and JNK3 (Fig. 1.2), therefore leads/drugs developed against JNK3 should be very specific (active against JNK3 at the same time inactive towards JNK1 \& JNK2) require specificity to avoid side-effects of drugs. Because due to highly similar sequence there is highest probability of a drug to bind any of these targets which causes adverse side-effects.

Fig. 1.6.1 : Multiple sequence alignment (MSA) of three JNK sequences determined using ClustalW. Important residues in JNK3 not common with JNK1 and JNK2 may be used for specific-JNK3 drug development

### 1.7 Scaffold Identification and its Impact on Drug Design

Scaffold is considered as a molecular fragment without any side-chain and a side chain is any acyclic chain or functional group with a single link point to remaining molecule. We can isolate scaffold and side-chains by detecting ring structure first. Starting are removed from the structure and retained as side-chains whereas remaining structure is stored as a scaffold.

Scaffold identification is process of finding relatively simple, often weakly potent, bioactive molecules that are "ligand efficient" i.e. most likely to bind a target. They possess a high binding affinity per heavy atoms and thus are ideal for optimization into clinical candidates with good drug-like properties. Because of the smaller and less complex nature of scaffolds, they increase the possibility of finding a match to the receptor. They have higher ligand efficiency thus provide greater scope for development when following a standard chemistry development strategy.

The four databases ACD, NCI, CMC and MDDR containing lead-like molecules were examined according to scaffold-based classification (SCA). The ACD was most diverse, followed by NCI, then CMC and finally MDDR. The objectives were to determine which fragments exist, how reccuring these are, how their occurrence related to one another and non-overlapping fragment in existing (drug) compound databases. Some scaffolds are found in pair in active compounds. Some scaffolds are not found in same compound. Two scaffolds may have same physiochemical properties therefore, they may not found in same molecule.

Some scaffolds occur more uncommonly (e.g. a phenyl ring) or chemical forms on which some drug classes are based. Some scaffolds have low occurence that might indicate rarely occuring parts of chemical space, potentially gripping for designing new compounds. Insights may provide preferences. Scaffolds that do not occur together, new chemical space can be analyzed. Their co-occurrences may be used to identify a replacement for a structural feature. Scaffold pairs barely occur together, possibly because of their similar physicochemical properties.

Fragment based screening have important role to find novel and patentable scaffolds. The core scaffold capable of binding to several target proteins may then further be optimized to a compound with appropriately balanced affinities between the target proteins.

We can group compounds into the same class if they have same topological scaffold in common. The aim backing for this was that chemists instinctively organize compounds based on scaffolds and functional groups.

### 1.8 Objectives

Keeping view of complexity of the disease and reported adverse side-effects of FDA approved drugs, the proposed study intend to use "Chemoinformatics" approach to suggest novel compounds against JNK3. So the followings are the objectives of the proposed work.
I. Developing database of inhibitors with their molecular data against JNK isotypes. 3D-structures of the compounds will also be provided to assist virtual screening.
II. To identify the fragments that are specific to our target and also the combination of scaffolds that are specific to one or more targets to be used for developing the most efficient drug against Alzheimer.

## CHAPTER - 2

## MATERIAL AND METHODS

Fig. 2.1 : Flow diagram of proposed work

### 2.1 Compounds

Approximately 700 Inhibitor structures and their inhibition activity against the AD drug targets JNK-isotypes and/or MAO protein(s) are collected from the literature. Experimental inhibition activities are reported in around 30 published papers. The structure of these molecules and their activity data are given below :

Table 2.1.1 : 1-Aryl-3, 4-dihydroisoquinoline inhibitors of JNK3 and p38a of compounds $52-142001 \mathrm{z}$, values in pIC50

### 2.2 Enrichment of Inhibitor Data

The structure of inhibitors and their activity were collected from literature. The information such as Molecular Formula, SMILES, IUPAC Name, Composition, etc data was generated for all the molecules to facilitate searching. Further, the physiochemical properties : LogD, LogP, Molecular Weight, Strongest acidic pKa , strongest basic $\mathrm{pKa}, \mathrm{H}$-bond donor $\&$ acceptor, etc for all the inhibitors were calculated using ChemAxon software. To facilitate query based on common names, traditional names of all the rings attached to inhibitors were identified and incorporated to the database. To determine fragments specific to an enzyme,
the inhibitor structures were fragmented on the basis of Bemis Murcko (Ring, Linker, SideChain \& Framework) method. All these data were processed and incorporated into AlzID database (http://14,139.240.55/AlzID/home.html).

Supplementary data will be provided in CD .

The following are the results :

Table. 2.2.1 : Data collection regarding the designed compounds (Ring, Formula, LogD)

### 2.3 Geometry Optimization

3D structures of these inhibitors are provided to assist virtual screening. The structures were drawn using MarvinSketch software available in ChemAxon.

Geometries were optimized using B3LYP (Becke's Lee Yang and Parr correlation) approach which is a hybrid functional algorithm that uses Becke's three parameters to mix in the exact Hartee-Fock Exchange correlation and Lee Yang and Parr (LYP) correlation functional that recovers dynamic electron correlation.

### 2.4 Fragmentation

Bemis Murcko Fragments i.e. ring, side-chain, linker and framework, of all the molecules were performed to facilitate faster analysis and co-occurrence studies. OpenEye's program OEChem and OEMedChem was used to generate fragments of each molecule.

```
package openeye.docexamples.oemedchem;
import openeye.oechem.*;
public class OEGetBemisMurcko {
    public static void main(String[] args) {
        // TODO Auto-generated method stub
                OEGraphMol mol = new OEGraphMol();
                oechem.OESmilesToMol(mol, "[H]c1ccc2c(c1)c(=NO)c(=0)n2Cc3ccccc(F)c3");
                for (OEAtomBondSet abset : oemedchem.OEGetBemisMurcko(mol)) {
                    OEIsAtomMember fragatompred = new OEIsAtomMember(abset.GetAtoms());
                OEIsBondMember fragbondpred = new OEIsBondMember(abset.GetBonds());
                    OEGraphMol fragment = new OEGraphMol();
                    boolean adjustHCount = true;
                    oechem.OESubsetMol(fragment, mol, fragatompred, fragbondpred, adjustHCount);
                    for (OERole role : abset.GetRoles()) {
                    System.out.printf("%s %s%n", role.GetName(), oechem.OEMolToSmiles(fragment));
                }
        }
    }
}
```

Fig. 2.4.1 : Openeye's Fragmentation code

### 2.5 Identification of Common \& Unique Fragments

Fragmentation dataset was analyzed to identify fragment patterns and their association with drug targets of Alzheimer Disease. We identified the traditional names of each ring of
molecules to analyze the frequency of fragments more than random in dataset by taking a particular threshold. We've also analyzed the frequencies of side-chain and linkers to get the pattern of fragments in dataset and to identify the association between the fragments for significant co-occurance. This analysis also assists to determine common and unique fragments.

### 2.6 Database Development

All the data were incorporated into "AlzID" Data resource (http://14,139.240.55/AlzID/home.html) to support access and retrieval of information. MySQL is used to generate queries and to retrieve information. Java Molecular Editor (JME) interface is provided to draw or upload structures of own choice. R's RCDK package is used for similarity searching based on fingerprints which further calculates similarity using "Tannimoto Coefficient".

### 2.7 Softwares Used

### 2.7.1 ChemSketch

It is software used for drawing chemical structures including organics, organometallics, polymers and Markush structures. It includes other features such as Calculation of molecular properties of molecules, their 2D and 3D structure cleaning and viewing and also the functionality for naming structures.

We used this software for designing our compounds and collecting SMILE Notation of respective compound. Compounds were stored in 2D (.png files) and 3D (.mol files) using this software.

### 2.7.2 ChemDraw

We used ChemDraw for cleaning the geometry of our structures \& to generate the IUPAC Names of all the molecules.

### 2.7.3 MarvinSketch

MarvinSketch was used to generate xyz files of all the molecules for optimization \& sdf files for generating the fingerprints of all the molecules for similarity searching.
Traditional names of ring were calculated for fragment analysis using MarvinSketch.

### 2.7.4 Instant JChem

Instant JChem was used to calculate the physiochemical properties such as LogD, LogP, Molecular Weight, Strongest acidic pKa, Strongest basic pKa, H-bond donor \& acceptor, Topological polar surface area, rotatable bonds, etc of all the molecules.

### 2.7.5 PuTTy

PuTTY is an SSH and telnet client. We used PuTTy for optimizing the geometry of our compounds using B3LYP algorithm.

### 2.7.6 OpenEye

Openeye's OEMedChem and OEchem package was used for fragmentation of each molecule into Bemis Murcko Fragments i.e. ring, side-chain, linker \& framework.

### 2.7.7 MySQL

MySQL is a Relational Database Management System (RDMS) which was used with PHP for the connectivity of our database to provide access and retrieval of information.

### 2.7.8 XAMPP

XAMPP is an integrated server package of Apache, MySQL, PHP and Perl. We used XAMPP to connect to localhost for executing our queries.

### 2.7.9 RCDK

RCDK is integrated CDK with R. CDK is Java library to support Chemoinformatics functionalities. We used RCDK to generate fingerprints of our molecules (approx. 700) and of query molecule to calculate the similarity between query and target molecules to provide desired library of molecules to the user.

## CHAPTER - 3

## RESULTS AND DISCUSSION

## ALZHEIMERS DISEASE INHIBITORS DATABASE

## (http://14,139.240.55/AlzID/home.html)

The database schema is organized relationally to make our database compatible with efficient loading, querying and updates. The resource presently contains data about 650 inhibitors. Data were prepared and validated for virtual screening. Inhibitors molecular properties were calculated so that user can get the "lead-like", "fragment-like" and "drug-like" molecules based on Lipinski's rule to evaluate drug-likeness or to determine if a molecule is biologically active or not. For this evaluation, we have provided molecular properties such as Molecular Weight, Hydrogen-bond donors, Hydrogen-bond acceptor, rotatable bonds, LogP etc.

## ARCHITECTURE OF DATABASE

Fig. 3.1 : Architecture of AlzID

AlzID resource contains information about inhibitors active against the Alzheimer disease's (AD) promising JNK-isotypes drug targets.

- Information to facilitate searching: Molecular Formula, SMILES, IUPAC Name, Bemis Murcko Fragments (Ring, Linker, Side-chain, Framework)
- Physicochemical properties: LogD, LogP, Molecular Weight, Strongest acidic pKa, strongest basic $\mathrm{pKa}, \mathrm{H}$-bond donor \& acceptor, etc
- Fragments that are unique or common to particular target
- Optimized 3D molecules (B3LYP/6-311G*) to assist computational drug discovery

All the data were incorporated into "AlzID" Database which uses the following architecture to store the data. Diverse queries are supported to access and retrieval of information.

## AlzID

INHIBITORS DATABASE

Fig. 3.3 : Front Page slider

## AlzID

## AlzID: ALZHEIMER DISEASE (AD) INHIBITORS DATABASE

AlzID resource contains information about inhibitors active against the Alzheimer disease's (AD) promising drug targets such as JNK-isotypes and/or MAO proteins. Side-effects of Alzheimer drugs are reported as major obstacle in the path of successful treatment. The c-Jun N -terminal kinases (JNKs) have major role in stress signalling pathways and the JNK3-isotype is expressed mainly in neuronal tissue. The JNK3 enzyme is highly expressed in post-mortem brains of individuals that suffered from AD. This enzyme has been found to play an upstream role in neuronal ischemic apoptosis. The loss of JNK3 protects the adult brain from glutamate-induced excitotoxicity and therefore, this enzyme is a promising drug target. However drugs targeting JNK3, due to similarity of this enzyme with other JNK-isotypes, are expected to produce side-effects. Consequently, the development of selective JNK3 inhibitors represents a useful approach may bring better treatment outcomes. Therefore, this resource has been developed to provide unique and common active fragments against drug targets of $A D$.
The selective expression of JNK3 in the brain, and the findings report that JNK3 knockout mice exhibit amelioration of neurodegeneration in animal models of Alzheimer's disease, suggest that the inhibition of this isoform would be a promising therapeutic option.

This resource provides the following information regarding inhibitors
Approximately 700 Inhibitor structures and their inhibition activity against the AD drug targets such as ACHE, BCHE, JNK-isotypes and/or MAO protein(s) are collected from the literature. Experimental inhibition activities are reported in around 30 published papers. Popular heterocyclic

## QUERY DESIGNING AND SEARCHING

The database provides users to search, browse and download molecules in pdb, SDF and mol formats. User can draw or upload the molecules in SMILES, SDF and mol2 format to get the libraries of their interest. Molecular structure can be drawn using Java Molecular Editor (JME) where user can click on "GET SMILES" button to get the SMILES of their molecule and choose the identity criteria like $90 \%, 80 \%, 70 \%, 60 \%$ or less for searching. SMILES may also be uploaded to search for library. We used R's RCDK package for similarity searching between the molecule or SMILES user upload and our dataset. We took input from users \& execution is done on R. RCDK generates the fingerprints of user uploaded molecule or SMILES and our dataset to search for similarity. It calculates similarity based on "Tannimoto Coefficient".

```
library(rcdk)
a<- load.molecules(c('com002.sdf', 'C:/Users/HP/Pictures/xampp/htdocs/alzid/alzid/com002.sdf'))
filename <- "sm.txt"
sd <- readChar(filename, file.info(filename)$size)
sf <- tostring(sd)
v <- parse.smiles(sf) [[1]]
query.fp <- get.fingerprint(v, type='maccs')
target.fps <- lapply(a, get.fingerprint, type='maccs')
sims <- unlist(lapply(target.fps,distance, fp2=query.fp, method='tanimoto'))
filei <- "iden.txt"
i <- readChar(filei, file.info(filei)$size)
hits <- which(sims > i)
write.table(hits, file = "c:/Users/HP/Pictures/xampp/htdocs/alzid/alzid/output.csv", sep = ",", col.names = NA,qmethod = "double")
hits
sims
|
```

Fig. 3.5 : RCDK code for Similarity Searching

The above code is used to generate fingerprints the molecules to calculate similarity based on tannimoto coefficient. Here 'com002.sdf' is combined sdf file of all the inhibitors in database, 'sm.txt' is a file containing the SMILES of compound user upload, whereas 'iden.txt' file contain the identity value i.e. $0.90,0.80,0.70,0.60$ so on user chooses to search for library of molecules.

\section*{METHODOLOGY}

Methodology page contains information regading the steps used for generation and compilation of data to further integrate it to data resource "AlzID". The steps include : structure \& activity data collection, geometry optimization, fragmentation, fragment analysis and database development.

\section*{AlzID}

\section*{FAQS}

Fig. 3.18 : Frequently asked questions regarding AlzID

The above figure showing the "FAQS (Frequently Asked Questions)" page that contain list of questions with answers that can be asked.

\section*{FRAGMENT ANALYSIS}

We mined our database of about 650 compounds which resulted over 2100 rings, 1300 linkers and 2400 side-chains. Fragment occurrence is very bias, with \(70 \%\) of fragments occurring only once and a few fragments such as pyrimidine, piperazine, indoline, thiophene and piperidine etc being present in many molecules. We identified the fragments that were occurring more than random in dataset. We took 7 as threshold in ring system and we identified set of common and unique fragment that were occurring 7 or more times.

In case of side-chain and linker, we took 3 as threshold as the frequency of occurring unique fragments was very few. So based on this threshold we identified set of common and unique fragments for JNK isotypes.

Table 4.1 : Scaffolds found to be unique against JNKs
\begin{tabular}{llc}
\hline Scaffold & Specific Enzyme & Frequency \\
\hline 2,7-phenanthroline & JNK3 & 10 \\
